# **Required Equipment**

- Windows PC or laptop computer
- "Straight-through" RS232 programming cable (or USB-to-RS232)
  - No longer than 6' (1.8 M)
  - RS232 pintout
    - 2 2
    - 3 3
    - 5 5
- XL200 Series machine controller
- 24VDC Power

# **XL200 Series Software and Hardware Versions**

The XL200 Series machine controller can be field flashed with new software versions, and it can be flashed with different software models. The software model and version supported by any XL200 controller depends on the hardware revision of the unit.

As products are developed, tested, and then subjected to the realities of a manufacturing environment - improvements are made in terms of reliability and performance. New features and functions desired by customers are added and refined.

The process of evolving hardware is tracked by a Revision Letter at AMS Controls. In terms of the XL200 Series machine controller, there is a CPU Board Revision Letter and an Input/Output (I/O) Board Revision Letter. The CPU board dictates the highest software version supported by a particular unit, and the I/O board revision indicates whether the unit supports open loop software, closed loop software, or both.

**V1 and V2 Controllers:** Rev. A & B I/O boards could only support open loop or closed loop, but not both. This means if you own a XL200 controller with a Rev. A or Rev. B I/O board, you must have AMS change out the board in order to go from open loop to closed loop software, or closed loop to open loop software.

## Latest Release by Version

Software versions 1 and 2 are no longer supported or developed.

Major Software Version Number	Final Release Version		
V1	V1.11 (open loop models), V1.13 (closed loop models)		
V2	V2.71.01 (all models)		

## What does the software version number mean?

Software versions are expressed as 3 sets of numbers separated by "points" (.). The first number refers to the *major software version* and often ties the version to a specific hardware revision. The second

number is a *major release version*. Every so often, the Engineering Department at AMS generates a "new release" that includes any new developments, features, functions and bug fixes since the last release. The last number is a *maintenance release version*, usually created in situations where a customer is experiencing a serious bug that affects production, or has paid for a new feature that they desire immediately.

Software Version Breakdown

# **XL200 Series Software Flashing Procedure**

Before attempting to flash a XL200 Series machine controller, users must contact AMS Controls for the appropriate flash file. The Flash Wizard software will usually be included in what is sent, or it can be downloaded from the <u>AMS Controls website</u>.

To create a flash file, AMS Support Technicians must know the hardware version, current software model, desired software model, software version, and serial number of the controller to be flashed. Often, they can find most of this information with only the serial number of the controller, assuming adequate records have been kept and updated.

XL200 controllers currently loaded with Version 1 software can only be tracked by serial number in terms of their hardware revisions. Version 1 software did not display the controller's hardware information to the user.

Version 2 and higher software models display all their pertinent information in a single menu – Diagnostics\System Information. A screenshot or picture of the system information screen will be requested by our support team to provide the correct file.

**XL200 System Information Menu** 

When the flashing software and new flash file are received, the flash file name should match the new software model, version and serial number. For instance, XL212\_v3\_45\_01\_sn7505.FMF.

# **Flashing Software by Revision and Version**

Different software versions and hardware revisions have slightly different procedures. Please verify your specific hardware and software versions to be sure you're using the correct procedure.

Authorization codes were always required by the original XL200 Flash Program software. Later, Flash Wizard was created and would often allow the user to program the XL200 Series machine controller without the need for an authorization code.

**Flash Wizard** does not require an authorization code if the software model does not change. That is, if the controller's software version is the only change, no code is required. If the software model will change with the flash, the user will be required to contact AMS Controls for an authorization code, unless AMS was contacted for the flash file, originally. Support Technicians can embed the controller's serial number in the flash file so that **Flash Wizard** will not prompt for an authorization code.

## V1& V2 Software for Rev. A Hardware

The first hardware generation of XL200 Series controllers required a different flashing program in order to change controller software model. The **XL200 Flash Program** was required, and this program <u>always</u> required the user to get an authorization code from AMS Controls. The code could not be generated ahead of time. The user must begin the flash process at the controller, receive a "flash code", contact AMS Controls with that code, and wait for an authorization code to be generated and sent back.

To flash a controller with Rev. A hardware:

#### \*\*\*WARNING\*\*\*

On Rev. A hardware models, the controller <u>must not lose power</u> or <u>lose communication with the</u> <u>laptop</u> during this process. If this occurs, you might not be able to recover and the unit will have to be shipped to AMS Controls to be re-flashed.

- 1. Remove power from the XL200 Series machine controller.
- 2. If the XL200 is on an Eclipse network, disconnect the B connector from the back of the XL200 controller before continuing with the flash process.

3. Connect the laptop to the XL200 using the RS232 cable. The laptop should be plugged into AC power. Most laptops switch to a "low power" mode when running on battery power. This can interfere with Com Port communication.

The RS232 cable should plug into the 9 pin port on top of the XL200 controller.

4. Start the XL200 Flash Program software. It will probably state "Comport not open", since the software defaults to COM 2, and most laptops do not have a COM 2.

Flash Program Software Pointed to Valid Com Port

6. On the XL200 Series controller, turn DIP switch 10 to the ON position. This puts the XL200 into Program Flash Memory mode the next time it's powered up.

DIP Switches on Top of XL200

7. Apply 24 VDC to the XL200 CPU inputs (A1, A2). The XL200 should power up with a blue screen with white lettering that reads "XL200 Program Flash Memory". Whatever appears on the XL200 screen should also appear in the XL200 Flash Program software screen, indicating the laptop and XL200 are connected and communicating with each other.

Note: The information in the following screenshot might not exactly match the data you see displayed on your laptop. This is normal.

#### **Flash Programming Completed**

- 13. Turn off power to the XL200 controller.
- 14. Disconnect the RS232 programming cable from the controller.
- 15. Re-connect the B connector if it was removed in Step 5.
- 16. Turn off DIP switch 10 on the top of the controller.
- 17. Turn on power to the controller. Answer whatever on-screen prompts are required to fully boot the unit to the Status menu.
- 18. Turn controller power off.
- 19. Press and hold the number "5" key on the keypad. While holding the "5" key down, re-apply power to the unit. Continue holding the "5" key until the following message is displayed:

	X	
The 5 key was pressed.		
<ul> <li>Clear ALL Memory</li> <li>Clear all memory EXCEPT setup parameters</li> </ul>		
Cancel OK		

**Clearing Memory after Flashing** 

- 20. Select the option for "Clear ALL Memory" and navigate to the OK button. Press the Enter key on the keypad.
- 21. Once the controller reboots, re-enter the unit's Eclipse data and let Eclipse download parameters, jobs, etc. into the controller. If the XL200 is not connected to Eclipse parameters, jobs, etc. must be re-entered by hand.

## V1& V2 Software for Rev. B Hardware

XL200 Series machine controllers with Rev. B hardware could be flashed with v1 or v2 software using the **Flash Wizard** program from AMS Controls. **Flash Wizard** is free software that can be downloaded from the AMS Controls website. Typically, a Support Technician will include a copy of **Flash Wizard** with the file to be flashed into the controller.

When using **Flash Wizard**, a Support Technician can embed the unit's serial number in the flash file when it's created. If this is done, the user will not be required to obtain an authorization code from AMS Controls. If this is not done, the user must begin the flash process in order to receive an authentication code. This code is given to a Support Technician who will generate the authorization code.

To flash a controller with Rev. B hardware:

### \*\*\*WARNING\*\*\*

On Rev. B hardware models, the controller <u>must not lose power</u> or <u>lose communication with the</u> <u>laptop</u> during this process. If this occurs, you might not be able to recover and the unit will have to be shipped to AMS Controls to be re-flashed.

- 1. Remove power from the XL200 Series machine controller.
- 2. If the XL200 is on an Eclipse network, disconnect the B connector from the back of the XL200 controller before continuing with the flash process.
- 3. Connect the laptop to the XL200 using the RS232 cable. The laptop should be plugged into AC power. Most laptops switch to a "low power" mode when running on battery power. This can interfere with Com Port communication.

The RS232 cable should plug into the 9 pin port on top of the XL200 controller.
